The voltage is low after inverter rectification

Overview

Why is the DC voltage low after rectification?

After the load is applied, the DC voltage after rectification is low, causing undervoltage failure. Countermeasure: Check whether the circuit breaker or contactor contacts of the inverter power supply are in good contact, whether the contact resistance is too large, whether the input voltage is normal, etc.

What causes undervoltage failure in an inverter?

1. Power supply phase loss Cause: When the inverter power supply phase is lost, the three-phase rectification becomes two-phase rectification. After the load is applied, the DC voltage after rectification is low, causing undervoltage failure.

What happens if a solar inverter is too low?

The open circuit voltage of the string should be much greater than the minimum input voltage of the inverter; if there are too few modules in series, the open circuit voltage of the string will be too low, resulting in no display on the inverter screen. Solution: Increase the number of solar panels in series.

Why is my inverter screen not working?

Reason 3: The DC input voltage is too low. When the string output voltage is lower than the minimum input voltage of the inverter, there is no display on the inverter screen. To make sure, you can use a multimeter to measure the output voltage of the photovoltaic string to see whether the voltage reaches the minimum input voltage of the inverter.
