What does the K value of solar container battery mean

Overview

What does K or C mean in a battery?

The capacity (K or C value) of a battery depends on the current with which it's discharged. The lower the discharge current, i.e. the longer the discharge time, the greater the usable capacity. And vice versa, the greater the discharge current, the less the available capacity. The "K or C" index always indicates the discharge time in hours.

What is k value of a lithium battery?

K value refers to the voltage drop of the battery in unit time, usually expressed in mV/d, and is an indicator to measure the self discharge rate of lithium battery. OCV1 is measured at time t1. Measure OCV2 at time t2.
 $K = \frac{OCV1 - OCV2}{t2 - t1}$ The K value of the battery with good performance is generally less than 2mV/d or 0.08mV/h.

What is a k-value in a lithium ion battery?

The "K-value" is a crucial parameter used to quantify the self-discharge rate of a lithium-ion battery. It represents the voltage drop per unit of time under specific conditions (e.g., high temperature or room temperature). A lower K-value generally indicates better battery performance. $K\text{-value} = \frac{OCV1 - OCV2}{t1 - t2}$.

Why do batteries have a k-value?

The K-value helps identify batteries with high self-discharge rates, enabling manufacturers to screen out defective units during production. Dust and Foreign Matter: Particles or debris can bridge the gap between the positive and negative electrodes, creating a direct current path and causing a continuous discharge.
